In the United States, approximately 250,000 people are diagnosed with a primary immunodeficiency disease (PI), and many more go undetected. Representing a group of more than 300 different rare disorders, primary immunodeficiencies are often difficult to diagnose. While not contagious, these diseases are caused by hereditary or genetic defects, in which part of the body’s immune system is missing or functions improperly.

Primary immunodeficiency disease can affect anyone, regardless of age or gender. While infection is the most significant symptom, be suspicious and ask your physician to check for the possibility of a primary immunodeficiency disease if the infection you or a family member experience is...

- **Severe** - requires hospitalization or intravenous antibiotics
- **Persistent** - won’t completely clear up or clears very slowly
- **Unusual** - caused by an uncommon organism
- **Recurrent** - keeps coming back
- **Runs in the Family** - others in your family have had a similar susceptibility to infection

Many people with primary immunodeficiencies live their entire lives more susceptible to infections, enduring recurrent health problems and often developing serious and debilitating illnesses. Fortunately, with proper medical care, many patients are able to live healthy and independent lives.
